1 Scope

2 This document defines the functional characteristics and the requirements of the
3 packet-switched Video Telephony (VT) services, sometimes also referred to as
4 Multimedia Conversational Services (MCS). Video Telephony is defined as one-to-one
5 video/speech communication capability. VT (MCS) should be used as a basis for
6 multiparty multimedia conferencing, but this is out of scope for the initial document
7 revision.

8 This initial effort is to be mindful of the continued development in subsequent phases
9 of the following enhancements (without implying any relative priority):

- 10 ➤ Interoperability support to other video telephony systems;
- 11 ➤ Capability of multipoint communication.

12 Hence the following two phases in the development of video telephony are defined:

13 **Phase 1:** Development of basic one-on-one video telephony functionality (Subject to
14 Stage 1 Revision A or earlier)

15 **Phase 2:** Enhancement for support of other video telephony systems and multipoint
16 communication (Subject to Stage 1 Revision B or later)

2 **4 Introduction**

3 The potential benefits of communicating via visual media, in addition to speech, have
 4 long been recognized, as greatly enhancing the potential for users to communicate and
 5 to convey information. Video telephony consists of ability of a user to simultaneously
 6 talk to another party, view video images from the other party, and send to the other
 7 party video images captured by local camera, stored in local device, etc. User can stop
 8 video communication without interrupting voice conversation.

9 Transmitting a video stream has proven to be a very challenging goal, since it requires
 10 significant resources, and therefore can place a heavy burden on the system. Because
 11 a video stream contains much more information than voice alone, it demands much
 12 higher data rate. In order to reduce the data rate, many video codecs are optimized for
 13 maximum compression alone, and thus are sensitive to transmission errors.

14 With the development of 3G wireless communications systems, the data rate available
 15 to each user can be considerably increased. The available network throughput has
 16 reached the threshold where reasonable quality video telephony services can be
 17 realized.

1 New developments in packet (IP based) networks as of late, have made video telephony
2 a more viable service due to some of the following:

- 3 ➤ Standardization of comprehensive QoS capabilities in all variants of
4 cdma2000^{®1} wireless networks;
- 5 ➤ Payload flexibility of packet switching and routing, which enables asymmetric
6 and variable rate bearers;
- 7 ➤ Optimization of wireline protocols for wireless networks (e.g. protocol header
8 compression/removal);
- 9 ➤ Increase in number of devices (PCs and laptop computers) frequently attached
10 to a network (wide area wireless, WLAN, or wired), in addition to the camera-
11 equipped wireless phones.

12 **5 Services and Features**

13 **5.1 Service Characteristics**

14 Packet-Switched Video Telephony provides two-way transmission of real-time
15 video, speech, combined speech/video, and other services in the wireless
16 communications systems. These services can be used in videophone,
17 multimedia video conferencing, long-distance classroom, video communications
18 in fieldwork, etc. Latency (round-trip delay between the parties) needs to be
19 kept to a minimum in order to support real-time information exchange between
20 the parties. In general, it is not feasible to recover transmission errors by
21 retransmission techniques, because of the delays involved in requesting
22 retransmission. Occasionally, video and speech quality may need to be
23 compromised to meet latency requirements. Video and speech codecs must be
24 robust enough to cope with the possibilities of errors in wireless transmission
25 channels. Intelligent use of error-recovery and error-concealment techniques is
26 desirable to ensure graceful performance degradation on noisy channels.

27 **5.2 Service Structure**

28 A VT terminal supports the capture, transport, and playback of real-time full-
29 duplex speech and video. The VT terminal contains a speech codec that
30 produces good voice quality and a video codec that produces reasonable video
31 quality. The terminal sets up, maintains, and releases video telephony sessions,
32 and transmits and receives the following data flows:

- 33 ➤ a low data rate packet loss sensitive control flow;
- 34 ➤ a low data rate and delay sensitive speech flow; and
- 35 ➤ a medium data rate delay sensitive video flow.

¹ cdma2000[®] is the trademark for the technical nomenclature for certain specifications and standards of the Organizational Partners (OPs) of 3GPP2. Geographically (and as of the date of publication), cdma2000[®] is a registered trademark of the Telecommunications Industry Association (TIA-USA) in the United States.

1 Assuming provision of adequate network resource (e.g. sufficient radio resource
2 capacity to handle the traffic load), video telephony services can in principle
3 exist alongside other wireless communication services without mutual impact.

4 VT services are symmetric between the parties in terms of available
5 functionality, which includes encoding, transmission, and decoding
6 components. However, to increase flexibility and optimize radio spectrum
7 efficiency, the services can be implemented without requiring symmetric bearers
8 on the forward and the reverse link, as well as to allow the user to add or drop a
9 multimedia component, and the operator to manage access based on the
10 network traffic load, QoS, etc.

11 Video and speech codecs encode the video and speech signals acquired by the
12 video terminal. After packetization, the encoded data is transmitted by the
13 wireless network, and delivered to the other participant of the VT call using the
14 Internet for transport and routing. At the same time, the VT terminal processes
15 incoming video and speech data from the remote participant by de-packetizing
16 them, then decoding this data with corresponding video and speech codecs. The
17 output is then played back at the local video/audio device.

18 Video telephony also includes system control protocols for setting up calls
19 between parties, exchanging and negotiating various options and capabilities,
20 and communicating with and controlling the various codecs used.

21 **6 Service Requirements**

22 **6.1 Terminology**

23 Some of the features and requirements listed below, though standardized, are
24 optional for a product implementation. Standards specifications are to be
25 developed regardless of this optional nature of a feature, so that those products
26 supporting them would operate consistently. To make optional/mandatory
27 distinction clear, use of terms is clarified as follows:

- 28 • The term "it shall be possible" refers to optional features that must be
29 allowed by the service. Subject feature is optional and its implementation in the
30 service is a decision for the operator.
- 31 • The term "shall" means that the feature is not optional to the service,
32 and must be supported in every implementation.

33 **6.2 System**

34 **VT-01. Backward Compatibility:** Packet-switched VT system in this document
35 should be interoperable with the packet-switched VT system defined in
36 S.R0106-0.

37 **VT-02. Interworking.** The VT system should be interoperable with international
38 standardized video conferencing systems (e.g., ITU-T H.324M [2]/ H.323 [1],
39 IETF RFC 3261 SIP [8]). It should be able to interconnect with 3GPP
40 circuit-switched VT. It should be able to exchange controlling information
41 with peers in format complying with international standardized protocol (e.g.,
42 ITU-T H.245, H.225.0). These requirements are applicable for Phase 2 of
43 packet-switched VT.

- 1 **VT-03. Media Component Transition.** It shall be possible to add or release a VT
2 multimedia component (e.g. video) without interrupting other multimedia
3 components (e.g. speech).
- 4 **VT-04. Media Component Transition Management.** When a terminal adds or
5 releases a multimedia component, this information shall be conveyed to the
6 correspondent terminal.
- 7 **VT-05. Addressing.** Both MDN and SIP URI addressing shall be supported.
- 8 **VT-06. Calling Party ID:** The system shall be able to provide the calling party ID
9 and an indication of the video telephony call to the called party, subject to
10 restrictions imposed by the calling party.
- 11 **VT-07. Mobility Management.** Provided system resources are available, it shall be
12 possible to maintain an uninterrupted a VT call when the VT user travels
13 within a PDSN coverage area and across multiple PDSN coverage areas that
14 support VT.
- 15 **VT-08. Roaming.** User shall be able to obtain VT service in the coverage area of a
16 visited PDSN that supports VT service.
- 17 **VT-09. Resource Optimization.** The system should be optimized to conserve the
18 processing power and other resources for the mobile station and base
19 station equipment, such as memory, power, spectrum (radio resources)
20 consumption, etc.
- 21 **VT-10.** Void.
- 22 **VT-11.** It shall be possible to provide VT service using the functionality of IMS.
- 23 **VT-12.** If the VT service is based on IMS, the VT user shall be a subscriber of IMS.
- 24 **VT-13.** It shall be possible for the VT user to originate a VT call on an HRPD access
25 network.
- 26 **VT-14.** It shall be possible for the VT user to receive a VT call on an HRPD access
27 network.
- 28 **VT-15.** It shall be possible to complete (accept) a VT call attempt made to a user
29 that is authorized for VT service but does not have VT service coverage by
30 connecting only the audio portion of the VT call.

31 **6.3 User Configuration**

- 32 **VT-16. Configuration Options.** User shall be able to configure the following on a
33 per-call basis:
- 34 a. Whether video or voice call is the preferred call origination type;
- 35 b. What multimedia components will be transmitted by the called party
36 upon accepting an incoming call;
- 37 **VT-17.** On-screen Display Mode: The user should be able to configure the display
38 mode as incoming or outgoing video, or both (e.g. picture-in-picture).

39 **6.4 Service Interaction**

- 40 **VT-18. Precedence over Data.** VT Service shall support the user ability to control
41 VT precedence over other delay tolerant data services of the same user. (See

1 also VT-24 QoS Control.)

2 **VT-19. Call Waiting Notification of Incoming Voice Call during a VT Call.** It
3 should be possible to notify a VT user of an incoming voice call. The VT
4 service should be able to maintain an ongoing VT call if an incoming voice
5 call notification occurs.

6 **VT-20. Call Waiting Notification of Incoming Video Telephony Call during a
7 Voice Call.** It should be possible to notify a voice call user of an incoming
8 VT call. An ongoing voice call should be maintained if an incoming VT call
9 notification occurs.

10 **VT-21. Priority.** VT service and voice service should have the same priority. The
11 VT service shall be able to maintain an ongoing VT call if an additional
12 incoming VT call occurs. The VT service shall be able to maintain an
13 ongoing VT call if an incoming voice call occurs.

14 **Note:** Voice service includes both circuit-switched cdma2000-1X voice
15 service and packet-switched VoIP service.

16 **VT-22.** Void.

17 **VT-23.** Void.

18 **VT-24.** Void.

19 **6.5 Video Codec**

20 **VT-25. Codec Selection.** A default codec should be recommended to minimize the
21 impact on Mobile Stations, and to eliminate or minimize the need for
22 transcoding schemes.

23 **VT-26. Picture Size.** The service should be able to provide services for
24 international standardized picture sizes, such as CIF and QCIF. It should
25 also support user agent (application) defined non-standard picture sizes.
26 Picture size shall be negotiable at initiation and during the VT call.

27 **6.6 Speech Codec**

28 **VT-27. Codec Selection.** A native 3GPP2 codec (see [3][4][5][6][7][11][12]) should
29 be the default codec in phase 1. A native 3GPP2 wideband codec (e.g. [12] in
30 Service Option 70 wideband mode) should be the default codec for wideband
31 speech capable terminals.

32 **Note:** Wideband speech refers to the increased fidelity of speech signal processing
33 made possible by increasing speech signal frequency band to about 7 kHz (16 kHz
34 sampling rate).

35

36 **VT-28. Error Concealment:** To improve voice quality, error concealment methods
37 in speech decoder may be included for the cases of excessive speech frame
38 loss and excessive jitter.

39 **Note:** In general, speech quality has more impact on user experience than
40 video quality. Therefore, the speech decoder should use one of more error
41 concealment methods. For example, when jitter limit is exceeded, buffer
42 underflow may occur and consequently frame skip may occur. Loss of a
43 speech frame due to radio transmission error has a similar effect. In those

1 situations, it is desirable to smooth the playback, not propagate to successive
2 frames. Note that error concealment methods are contained solely within the
3 mobile station receiver and are not subject to standardization. They are
4 included here since their implementation affects user experience.

5 **6.7 Packetization**

6 **VT-29. Transport.** Protocol header compression or removal schemes should be
7 supported on point-to-point transmission segments within the wireless
8 network.

9 **VT-30. Payload.** RTP (see [9]) shall be used for media packetization. RTP payload
10 schemes should be recognized and recorded in the IETF (Audio/Video
11 Transport Working Group).

12 **6.8 Media Adaptation**

13 Media adaptation at the video terminals to dynamic changes in the network conditions
14 can be used to achieve improved performance. These dynamic changes are observable
15 at the end terminals and can be fed back from the receiver (video decoder) terminal to
16 the sender, triggering an appropriate action at the sender (video encoder) terminal to
17 adapt to such reported network conditions within the granted QoS levels of the network.

18 The terminal is not required to support such media adaptation. During the PSVT
19 session setup, the end terminals signal their capabilities to support such feedback
20 mechanisms that enable media adaptation.

21

22 **VT-31. Video Adaptation.** It shall be possible for the sender terminal to adapt
23 source encoding to the network conditions reported from the receiver
24 terminal. This capability shall be possible in either directions of media flow.

25

26 **7 QoS Requirements**

27 In order to provide end users with multimedia conversational services of acceptable
28 quality, specific QoS requirements are imposed. Acceptable performance levels
29 mandate specific minimum end-to-end QoS levels. To meet those end-to-end
30 requirements, QoS requirements for the wireless communication portion of the link also
31 need to be met. QoS parameter limits in the wireless portion need to be somewhat
32 more stringent than the required end-to-end QoS, so as to apportion a part of the QoS
33 “budget” to the rest of the link. Unless explicitly noted, the QoS specifications herein
34 apply if the link is controlled by the wireless network end-to-end. For the case where
35 one end of the communication link is outside of the wireless communications network,
36 or it does not support QoS, the QoS requirements apply only to the portion that is
37 within the wireless network.

38 **7.1 General**

39 **VT-32. Admission.** The network shall have the capability to admit or block an
40 attempted VT service instance, based on QoS conditions in the network and
41 radio channel conditions necessary for successful execution of the VT

1 service.

2 **VT-33. Data Rate Variability.** It should be possible to vary transmission rate for
3 VT by adapting to speech/video source content, so as to maximize radio
4 network capacity.

5 **7.2 QoS Attributes**

6 The QoS attributes relevant for video telephony are listed in 8.2.1 through 8.2.6.

7 **VT-34. QoS Attribute Control.** The video telephony service entities should be able
8 to set up values of QoS attributes defined in sections 8.2.1 through 8.2.6 at
9 call setup. If not specified during setup negotiation, default value set by the
10 network should be used.

11 **7.2.1 Maximum and Average Data Rate (kbps)**

12 Definition of Maximum Data Rate: The maximum number of bits
13 (summed over all multimedia components in a VT call) delivered in a
14 frame, divided by the frame duration.

15 Definition of Average Data Rate (ADR): Number of bits summed over all
16 multimedia components and over a segment of a VT call divided by the
17 duration of the segment.

18 Average and Maximum Data Rates selection should be enabled to allow
19 specification of the target grade of service. Maximum channel data rate
20 should be a configurable parameter that operator can set.

21 **7.2.2 Maximum Video Frame Rate (fps)**

22 Definition: The maximum number of video frames per second (fps).

23 Frame rate may be changed during a VT call as a function of source
24 content or other considerations.

25 **7.2.3 Maximum Transfer Delay (sec)**

26 Definition: The maximum delay for 95th percentile of the distribution of
27 delay for all delivered data frames during a call. The delay is measured
28 from the time of a video frame capture and from the beginning of an
29 audio frame (segment) at the sending party, to the output of that same
30 video/audio frame at the receiving party video and audio decoders.

31 Example audio delay: 0.5 sec.

32 Example video delay: 1.0 sec.

33 **7.2.4 Inter-Media Skew (sec)**

34 Definition: Level of synchronization between the video and the speech
35 component in a VT call.

36 Example: 0.500 sec 90% of the time.

37 **Note:** The system design permits separate IP packet flows for speech
38 and video. In general, it is not required for the network to coordinate

1 quality of service control across multiple IP packet flows. Since buffering
 2 can be used at the terminal to control the inter-media skew, the inter-
 3 media skew requirement is a terminal requirement rather than a
 4 network requirement.

5 **7.2.5 Frame Error Rate**

6 Definition: The rate of lost and corrupted data units (e.g., octets, RLP
 7 frames, video packets) in the transmitted data:

8 Note: The use of Frame Error Rate is expected to meet the following
 9 guidelines:

- 10 1. The frame error rate parameter(s) specifies the maximum acceptable
 11 lossiness in the radio network for the VT application.
- 12 2. The frame error rate parameter(s) can be correlated to the video
 13 quality perceived by the user (e.g. mean opinion score) for a given
 14 video codec.
- 15 3. The frame error rate parameter(s) is translatable to radio link
 16 parameters that the radio network can use to control the radio link
 17 lossiness.

18 **7.2.6 Jitter (sec)**

19 Definition: Fluctuation of arrival times of frames (video or speech). It is
 20 expressed by standard deviation of arrival times of frames relative to the
 21 expected (clocked) times.

22 **7.3 Control of VT Parameters**

- 23 **VT-35. Target Data Rate.** Under normal traffic/channel conditions, the video
 24 encoder should maintain a target peak and average data rate based on the
 25 default or originally negotiated service parameters (e.g. 56 kbps including
 26 RTP overhead).
- 27 **VT-36. Frame Rate.** Video encoder frame rate shall be configurable. The encoder
 28 shall adjust the frame rate and frame quality so as to not exceed the target
 29 bit rate. The encoder shall support the default frame rate.
- 30 **VT-37. Dynamic Setting of Parameters.** The service should be able to dynamically
 31 negotiate VT service parameters (e.g., bit rates, picture size, multimedia
 32 components, etc.) during the session, to adapt to the users' needs and/or
 33 channel conditions.
- 34 **VT-38. QoS Control.** User, User Agent, and/or network-resident proxy shall be
 35 able to specify QoS parameters, based on interaction between these VT
 36 service entities and the appropriate QoS control network entity. This is to
 37 enable the selection of the VT service quality that best fits user needs, and to
 38 permit the user to control the service, within bounds imposed by the
 39 network and/or subscription.
- 40 **VT-39. Service Parameter Control.** The user should be able to control certain
 41 service parameters any time during a VT call, subject to constraints of the
 42 link and network load conditions. These controls should include:
- 43 a. Negotiate to drop or add a multimedia component;

- 1 b. Negotiate to increase or decrease video frame rate;
 2 c. Negotiate to increase or decrease picture resolution;
 3 **VT-40. Application Control of QoS:** VT should make best effort to maintain an
 4 application level QoS.

5 **Note:** If the network is unable to deliver the requested level of QoS, the VT
 6 application in the terminal should adjust the application QoS to the
 7 network/link condition by means of one of the following:

- 8 a. Obtain RAN condition by referencing the appropriate network control
 9 entity;
 10 b. Obtain end-to-end condition visible to the application, if the RAN
 11 information is not available.

12 When unable to maintain the requested service parameters, the VT application
 13 in the terminal should do one of the following:

- 14 c. Drop video/speech frames;
 15 d. Instruct the local VT terminal to decrease the outgoing frame rate, lower
 16 per-frame quality, discontinue transmitting a multimedia component, or
 17 any combination thereof;
 18 e. Request the remote VT terminal to decrease the outgoing frame rate,
 19 lower per-frame quality, discontinue transmitting a multimedia
 20 component, or any combination thereof;
 21 f. Discontinue transmitting an incoming multimedia component to the
 22 local VT;

23 Both calling and called parties should be notified if transmission of a media
 24 component had been discontinued. Note that this notification may be
 25 implicit.

26 Steps to downgrade VT service QoS should occur only after services that do
 27 not support QoS (implicitly require only best-effort QoS) have been
 28 downgraded first.

29 Upon restoration of channel/traffic conditions, the VT application in the
 30 terminal should restore the originally negotiated service parameters by
 31 reversing the above mentioned controls.

32 **8 Security**

33 **VT-41. Service Authentication.** In addition to Access Authentication, the network
 34 should be able to perform VT service authentication at an appropriate time
 35 (e.g., VT origination, VT termination).

36 **VT-42. Encryption.** VT should support end-to-end encryption providing confidence
 37 for business customers to conduct sensitive communications using VT.

38 **9 Accounting**

39 **VT-43. Accounting Records.** The following accounting records should be provided:
 40 a. Negotiated QoS parameters or a relevant set thereof (some may be

- 1 default, others are subject to end-to-end QoS and may not be used in the
2 accounting record analysis)
- 3 b. VT call duration
- 4 c. Time of day
- 5 d. Volume of data transmitted/received
- 6 e. IP packet count
- 7 **VT-44. Advice of Charge.** User should be advised of a possible change of tariff or
8 tariff differential due to roaming status or time of day of the call. This
9 notification may be implicit.

10 **10 Use Cases and Call Scenarios** 11 **(Informative)**

12 Use cases describe PSVT situations in the context of a system that supports both the
13 circuit-switched (CS) cdma2000 1x network, and the packet-switched (PS) HRPD
14 network. Some call scenarios are described with the purpose of illustrating video
15 telephony use cases and interactions with voice telephony services.

16 **a. VT Call Origination on HRPD Network**

17 Use Case 1: The VT subscriber camping on the HRPD network, which may or
18 may not have previously established a packet data session, originates a VT call.

19 Use Case 2: The VT subscriber already engaged in a VT call places another VT
20 call thus establishing a 3-way video conference.

21 **Note:** This use case is subject to Phase 2 of PSVT specifications.

22 **b. VT Call Termination on HRPD Network**

23 Use Case 3: The VT subscriber camping on the HRPD network, having
24 previously established a packet data session and being registered on IMS,
25 receives an incoming VT call.

26 Use Case 4: The VT subscriber is already engaged in a VT call. When an
27 additional incoming VT call occurs, VT call waiting indication is presented to the
28 subject subscriber.

29 **c. VT Call Hand-down to Voice Call**

30 Use Case 5: The VT subscriber is on a VT call on the HRPD network. When the
31 HRPD network becomes unavailable to the VT subscriber, the video component
32 of the call is removed, and the call is handed off to the cdma2000 1x network as
33 a voice call.

34 **d. VT Call Exceptions**

35 Use Case 6: The calling party attempts a VT call to a user who is not an IMS
36 subscriber, or does not have VT subscription. The call is established as a CS

1 call on cdma2000 1x.

2 Use Case 7: The calling party attempts a VT call to a VT subscriber who is out
3 of the HRPD coverage. The call is established as the CS call on cdma2000 1x.

4 Use Case 8: A VT subscriber is active in a cdma2000 1x voice call. The
5 incoming VT call is delivered as cdma2000 1x CS voice call. CS call waiting
6 indication is presented to the subject subscriber.

7 Use Case 9: A VT subscriber is active in a cdma2000 1x packet data call. The
8 network and the terminal device have VPOP capability. The incoming VT call is
9 delivered as a cdma2000 1x CS voice call.

10 Use Case 10: A VT subscriber is active in a VT call. The incoming voice call is
11 delivered as an HRPD VoIP call.

12 **e. Normal VT Call Flow**

13 The calling party originates a VT call. The called party is alerted of the incoming
14 VT call. The calling party ID is displayed. The called party accepts the VT call,
15 speech and video media start flowing, and the call is established successfully.

16 **f. Unsuccessful VT Call**

17 **VT Call Rejection:** The calling party originates a VT call. The called party is
18 alerted of the incoming VT call. The calling party ID is displayed. The called
19 party rejects the VT call. The calling party is notified that the VT call has failed
20 due to the rejection by the called party, and the calling party is presented with
21 the option to leave a video mail if supported.

22 **Failure Due to Resource Limitation:** The calling party originates a VT call.
23 The VT call fails because the called party terminal does not support VT, or there
24 are inadequate network resources to complete the call. The calling party is
25 notified that the VT call has failed and the failure cause. The calling party is
26 presented with an option to proceed by making a voice call.

27 **g. Fallback of VT Call**

28 If the network resources are inadequate to sustain a VT call in progress, VT
29 terminal gracefully downgrades the video quality while maintaining speech flow
30 until the video flow is discontinued.

31 When adequate network resource becomes again available, the video flow may
32 resume.

33 A party engaged in a VT call can mute/fade outgoing speech/video during VT
34 call.

35 **h. Incoming Voice Call during VT Call**

36 An incoming voice call does not automatically terminate an ongoing VT call.
37 The system indicates to the VT user that a voice call is waiting. The VT user
38 chooses whether to place the VT call on hold and accept the voice call.

1 **i. Incoming VT Call during VT Call**

2 If an incoming VT call is placed to a VT user during an ongoing VT call, the
3 system indicates to the VT user that another VT call is waiting. The VT user
4 chooses whether to place the ongoing VT call on hold and accept the VT call.

5 **j. Teardown of VT Call**

6 The calling party or the called party can tear down an ongoing VT call at any
7 time.
